the combination of exposure to each of the factors is necessary to change in the number of people infected with the virus.

in addition, the study also suggests that alcohol intake, smoking, and physical activity levels may play a role in the severity of the disease. these factors were found to be associated with a lower risk of hospitalization and death among infected individuals.

overall, the findings of the study highlight the importance of understanding the complex interplay between biological, environmental, and behavioral factors in the development and progression of the disease.
